INTRODUCTION

This section is intended to provide an overview of MITEQ's passive and active multiplier capabilities. Within this catalog you will find a variety of standard designs which will meet typical applications. However, MITEQ maintains dedicated engineering resources to modify these standard designs in support of custom-generated specifications that are typically required in stringent system applications. These critical requirements often require high spectral purity. MITEQ can obtain high levels of fundamental and spurious signal

suppression as required in many frequency source applications by employing special filter technologies.

In addition to custom-filter designs, MITEQ also has advanced amplifier technologies which, when combined with balanced multiplier designs, offer high performance active multipliers especially in the areas of shaped frequency response and desired output levels.

TECHNICAL OVERVIEW

Most of MITEQ's frequency multiplier designs perform to specific customer requirements and cannot easily be categorized into standard products. Parameters such as frequency range, bandwidth, spurious rejection and multiplication ratios are normally determined by specific system requirements. These requirements, in turn, translate into custom-designed filter and amplifier specifications at the multiplier design level.

In most frequency multiplier designs, the multiplier output contains, besides the desired harmonic output, unwanted signals. These unwanted signals consist of the fundamental input signal leakage, and lower-order and higher-order harmonics generated in the multiplier. Quite often with odd-order multipliers, the undesired signals are higher in level than the desired signal. In even-order multipliers, the undesired outputs are normally 10 to 20 dB below the desired output. Thus, the output signals can be amplified before the output is filtered. This is not possible with odd-order multipliers because the unwanted signals will cause the amplifier to saturate and suppress the desired output.

Definitions of key performance parameters vary from manufacturer to manufacturer. Some of the variations are minor, while others can lead to misinterpretations of specifications. In order to avoid that problem and facilitate the use of this catalog, we have supplied a technical discussion for our series of passive and active multipliers.

MULTIPLIER LOSSES

The basic multiplier losses of MITEQ's passive multipliers are listed below;

times two (X 2):	12 dB typical
times three (X 3):	17 dB typical
times four (X 4):	22 dB typical
times five (X 5):	23 dB typical

MITEQ's active multipliers are formed by cascading a passive multiplier and an active device, such as an amplifier. Multipliers of higher orders are formed by cascading these basic blocks. The most common higher-order multiplier used for MITEQ's systems applications is the times six, which is formed with the cascade of times two and times three. MITEQ manufactures C-band through Ku-band multipliers with built-in comb bandpass filters, MMIC amplifiers and higher-order assemblies that include various combinations of even- and odd-harmonic multipliers.

PHASE NOISE

MITEQ multipliers add phase noise to a lower frequency source by approximately $20 \times \log [N] + 3$ dB, where N is the multiplication factor. If spurious products are present on an incoming signal, they increase in level by this factor. Below is a visual representation of this phenomenon:

One method of measuring the phase noise contribution is referred to as a residual phase noise measurement and requires three multipliers (three measurements with two multipliers each), so that the source noise is cancelled. At present, all of our multipliers have not been thoroughly characterized for phase noise contribution.

SPURIOUS AND HARMONIC REJECTION

The concepts of harmonic rejection and spurious rejection are very important in the manufacture of multipliers. An important tool in the design process relates to the spurious-free bandwidth, which can be mathematically calculated from the relation:

$$[N + 1] / N \leq [\text{upper frequency limit} / \text{lower frequency limit}]$$

where N is the multiplication factor.

For a tripler, this ratio becomes $4/3 = 1.333$. A tripler whose output is 4 to 8 GHz wide has inband spurious outputs that are not filtered because $8/4 = 2$, which exceeds the spurious-free bandwidth ratio.

With regard to spurious rejection, it makes a difference over what output region the rejection is required. Generally, MITEQ produces multipliers with -65 dBc minimum spurious rejection not only in the output passband, but also outside the desired passband from (1 to 18 GHz). Spurious outputs take three basic forms.

- CASE 1. The spurs are not harmonically related to the input and are called nonharmonically-related spurs [not related to N at all].
- CASE 2. The spurs are related somehow to the input, or multiples of it, and are called harmonically-related spurious. [N + 1, N - 1, N + 2, etc.].
- CASE 3. The spurs are related to multiples of the output and are referred to as output harmonics [N, 3N, 4N, etc.].

At MITEQ, we refer to the first two cases under the general term spurious rejection and to case three by the term output harmonics. Rejection to output harmonics for the vast majority of MITEQ multipliers lies between -15 and -20 dBc. The reason for this is because those multipliers that require amplification usually employ an amplifier that is run in a saturated mode to minimize output power variations versus temperature.

This leads to a key design concept about properly assessing the choice of multiplication factor, and more importantly, how much rejection is required to meet your overall system requirements. The multiplier can be used as part of a synthesizer or source that feeds one port of a mixer. When the spurs of the multiplier enter the mixer, they mix with the RF and its harmonics to produce various unwanted signals that cannot be filtered in the IF passband.

DESIGN EXAMPLE

Your system requires a multiplier output from 8.6 to 10.5 GHz. Due to the available input frequencies, it is determined that the multiplication factor is six times. This is best accomplished by cascading a times three and a times two multiplier.

The input required for the tripler will be 1433 to 1750 MHz.

Multiples of the input, present at the output are:

X 2	2866 – 3500 MHz
X 3	4299 – 5250 MHz [desired]
X 4	5732 – 7000 MHz
X 5	7165 – 8750 MHz etc...

Suppose that the times five spectral component at the output is not suppressed properly. If your system specification is -70 dBc spurious, for example, and the $N + 2$ product is only suppressed by -58 dBc, the times six chain will not meet specification, because the next doubler will not provide any additional suppression. This product is an inband spurious because anything from 8600 to 10500 MHz is inband.

Suppose, next, that the $N + 1$ product of the tripler is not suppressed -70 dBc. The desired input to the doubler is 4299 to 5250 MHz, but we also have an input from 5732 to 7000 MHz that was not adequately suppressed. Therefore, we will observe an undesired output from the doubler at the following frequency:

$N + 1$	5732 – 7000 MHz
N	4299 – 5250 MHz, the difference product is 1433 – 1750 MHz

Since our desired output is 8600 to 10500 MHz, the difference product maps into the region (8600 to 10500 MHz) + (1433 to 1750 MHz) and the result is 10033 to 12250 MHz, which is an undesired product, from at least the 10033 to 10500 MHz region of the desired output passband.

The point of this example is to show that when a multiplier system is designed from cascaded multipliers, potential problems exist if you buy the individual multipliers separately from MITEQ and do not take into account all the multiples and their products formed at various stages. MITEQ provides custom-designed higher-order multipliers that will not suffer from these effects.

SPECIFICATION DEFINITIONS

PASSIVE MULTIPLIERS

CONVERSION LOSS (also known as multiplier loss)

This is the attenuation in dB between the input level and the output level.

HARMONIC REJECTION

The difference in dB between the desired harmonic and the unwanted harmonic as viewed at the multiplier output port. When the unwanted harmonic is the fundamental itself, then the difference is the fundamental rejection.

ACTIVE MULTIPLIERS

CONVERSION GAIN

The net increase in power between the fundamental input signal and the desired output. It is usually expressed as a positive ratio in dB.

SPURIOUS REJECTION

The difference in dB between the desired output harmonic and any other harmonic as viewed at the multiplier's output. The spurs can be multiples of the input frequency.

OUTPUT HARMONIC REJECTION

The difference in dB between the desired output and harmonics of the output frequency.

COMMON DEFINITIONS FOR BOTH PASSIVE AND ACTIVE MULTIPLIERS

OUTPUT POWER FLATNESS

The maximum power variation in dB over a specified frequency and at a specific temperature.

INPUT POWER

The level in dBm as measured at the multiplier's input port.

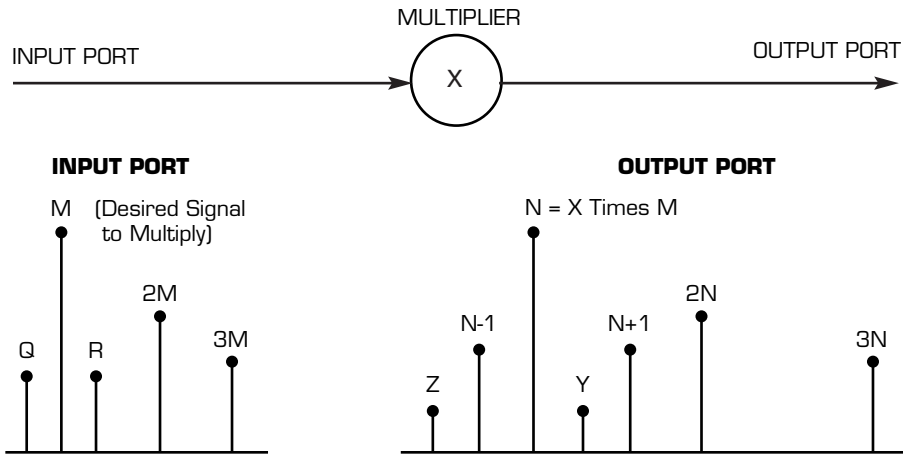

OUTPUT POWER

The level in dBm as measured at the output port of the multiplier.

OPERATING TEMPERATURE

The temperature range at which the device meets the specified electrical parameters. The temperature is defined as the base plate temperature of the device.

DEFINING MULTIPLIER TERMS

Input harmonics feeding multiplier = $2M, 3M$
 Spurious feeding multiplier = Q, R

Output harmonics from multiplier = $2N, 3N$
 Input harmonic rejection (products generated in the multiplier) = $N + 1, N - 1$ related to the input
 Spurious rejection = Y, Z

TYPICAL BLOCK DIAGRAMS

The basic use of frequency multipliers is to extend the output frequency range or bandwidth of a source by multiplying that frequency by a given multiplication factor, i.e., twice the fundamental of a 5 to 10 GHz source would yield a 10 to 20 GHz output. The following block diagrams represent but a small sampling of the uses for both passive and active multipliers.

PASSIVE MULTIPLIERS

ACTIVE MULTIPLIERS

SUBSYSTEM WITH MULTIPLIERS

SPECIFICATIONS AND TYPICAL VALUES

One very common problem MITEQ's customers face when purchasing multipliers is not knowing what specifications are practically realizable, and also not appreciating that over specification causes large, bulky and expensive products. This can be overcome by using some practical values established here as a reference:

SPECIFICATION	TYPICAL VALUE
Multiplication factor	Examine spurious-free bandwidth ratio
Phase noise contribution	$20 \log [N] + 3 \text{ dB}$
Output bandwidth	Examine spurious-free bandwidth ratio
Input power	+10 dBm
Output power	+10 dBm
Output power flatness	$\pm 1.50 \text{ dB}$
Spurious rejection	-50 to -60 dBc for designs with filters
Output harmonics	-15 dBc
Operating temperature	0 to 50°C
Size	Depends on required rejection

ENVIRONMENTAL CONDITIONS

MITEQ's standard frequency multipliers have been designed to meet the following environmental conditions:

Operating temperature	-30 to +75°C
Storage temperature	-40 to +85°C
Humidity	95% relative humidity, noncondensing
Vibration	7 g's rms, 50-5000 CPS, per MIL-STD-810B, Method 514, Procedure 5
Data curves are at 25°C	There will be some variation in the typical data shown as a function of temperature

PERCENTAGE BANDWIDTH, REJECTION AND SIZE

The last topic to address is perhaps the most complicated. It relates to having some feel for how large a multiplier will be in order to achieve proper spurious rejection. Two diagnostic tools used at MITEQ are presented here, which have played an important role in this regard:

Multiplier Percentage Bandwidth = $[\text{Output Bandwidth}] / [\text{Operating Frequency}]$
MITEQ produces designs with 10 to 15 percent bandwidths.

Bandwidth Ratio = $[\text{Reject Frequency} - \text{Center Frequency}] / [\text{Output Bandwidth}]$
Generally, the higher the number the better.

When the percentage bandwidth gets too large, and/or when the bandwidth ratio gets too small, the multiplier becomes difficult to produce and may become quite large because the filtering requirements are forcing the number of filtering elements to increase. It is also true that the size is related to the operating frequency.

Since the filter is often the largest component of the multiplier, it is useful to know how many resonators are needed and how large your multiplier might be. MITEQ has engineering support available to help you get a feel for how large your multiplier might be. **Contact MITEQ at (631) 439-9220** to discuss the details about specifying the spurious rejection and size of your multiplier requirement for a cost-effective design.

ACTIVE FREQUENCY MULTIPLIERS

TYPICAL PERFORMANCE VS. INPUT POWER

INPUT RETURN LOSS VS. INPUT POWER FOR J DRIVE LEVEL MULTIPLIERS

INPUT RETURN LOSS VS. INPUT POWER FOR M DRIVE LEVEL MULTIPLIERS

INPUT RETURN LOSS VS. INPUT POWER FOR V DRIVE LEVEL MULTIPLIERS

OUTPUT VS. INPUT POWER LEVEL FOR M AND V DRIVE LEVEL MULTIPLIERS

AVAILABLE INPUT POWER OPTIONS

DRIVE LEVEL	INPUT DRIVE (dBm)
J	3 – 8
M	8 – 12
H	12 – 16
V	16 – 20

COMMON APPLICATIONS

SATCOM PRODUCTS - COMMUNICATIONS RECEIVERS

Microwave front ends usually employ a phase-locked source, such as a frequency synthesizer which has extremely low phase-noise characteristics, especially for digital communications. The synthesizer uses a fundamental VCO which is locked to highly-stable crystal reference sources. The frequency limitation of many commercial VCOs and frequency dividers is 3500 MHz. A multiplier is employed to extend the synthesizer range.

RADAR RECEIVERS

Most radars employ frequency synthesizers which require frequency multipliers. The phase noise must be low to avoid clutter noise.

INSTRUMENTATION APPLICATIONS

Frequency synthesizers which require multipliers are found in the front end of many measuring instruments which require low phase-noise LOs. One example is a spectrum analyzer.

RADIO ASTRONOMY APPLICATIONS

Interferometers and radiometers require broadband frequency doublers for wideband receivers. Frequency synthesizers are used to generate millimeter-wave frequencies to make the measurements.

MILLIMETER-WAVE SOURCES

Millimeter-wave frequencies are used in research applications for atomic spectroscopy and for various communications and radars. A multiplier chain can be used to generate these frequencies from a lower frequency source.

FREQUENCY STANDARDS

Highly-stable frequency sources can be multiplied to produce microwave sources used to measure the effect of the atmosphere or rocket exhaust on microwave signals.

NOTES:

- (1) Available with WR42 on output.
 - (2) Available with WR28 on output.
 - (3) Available with WR22/WR19 on output.
 - (4) Requires negative bias -15 V at 70 mA.
 - (5) Requires negative bias -5 V at 50 mA.
- * Detailed specification sheet inside catalog.

* Detailed specification sheet inside catalog. Data taken with +12 dBm drive.
 ** No negative voltage required for this product.
 NOTES: These multipliers are designed with printed filters, and for lower cost than tunable products. The frequency plans can be easily changed with slight filter modifications.

4 TO 40 GHz OUTPUT LOW-NOISE FREQUENCY DOUBLER

MODEL: TD0040LA2

FEATURES

- RF input..... 2 to 20 GHz
- RF output 4 to 40 GHz
- Conversion loss 13 dB typical
- Isolation F_{in}/F_{out} 30 dB typical
- Output phase noise equivalent to passive Schottky diode mixer

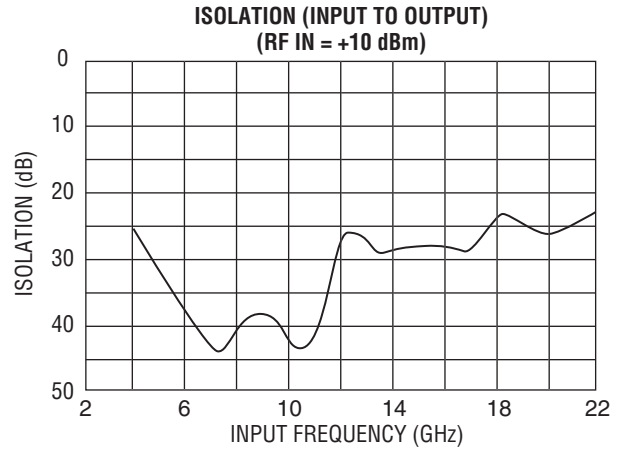

This triple-balanced passive frequency multiplier is useful as a signal source in millimeter receivers or transmitters. A minimum input power of +10 dBm is required to achieve -3 dBm output using low-level diodes. Higher level diodes will yield +5 dBm output with +20 dBm input. An active version is also available with a +10 dBm output utilizing MITEQ's low-noise amplifiers.

ELECTRICAL SPECIFICATIONS

INPUT PARAMETERS	CONDITION	UNITS	MIN.	TYP.	MAX.
RF frequency range		GHz	2		20
RF VSWR		Ratio		3:1	
RF power range		dBm	+7	+10	+13
TRANSFER CHARACTERISTICS	CONDITION	UNITS	MIN.	TYP.	MAX.
Conversion loss (RF = +10 dBm)	4 to 40 GHz	dB		15	18
	12 to 32 GHz	dB		13	15
	18 to 26 GHz	dB		11	13
Isolation RF in to RF out	4 to 40 GHz	dB	20	25	
	12 to 32 GHz	dB	25	30	
	18 to 26 GHz	dB	27	33	
OUTPUT PARAMETERS	CONDITION	UNITS	MIN.	TYP.	MAX.
IF frequency range		GHz	4		40
Power diode	L	dBm		-3	
	H	dBm		5	
Active option	Input = +10	dBm		12	

TD0040LA2 TYPICAL TEST DATA

MAXIMUM RATINGS

Specification temperature..... +25°C
 Operating temperature -54 to +85°C
 Storage temperature -65 to +125°C

GENERAL NOTES

1. Input or output LNAs available.
2. Existing package is hermetically sealed.
3. Burn out = +23 dBm input.

NOTES:

1. Unit's mounting surface shall be attached to a heatsink capable of dissipating the device's power consumption without exceeding the operating temperature limits.
2. Refer to the actual device specification sheet for bias requirements. Negative bias input voltage (v-) may not be included on certain models.
3. Unless noted on the specification sheet, when negative bias is required, do not power the unit with positive bias for more than one second without the negative bias being applied.
4. All dimensions shown in brackets [] are in millimeters.

ACTIVE 2X FREQUENCY MULTIPLIER

0.15 TO 3 GHz, (X20) MULTIPLIER SUBSYSTEM

MODEL: SYS20M028032

FEATURES

- Input/output frequency 0.15/3 GHz
- Input/output BW 10 percent
- Spurious (octave BW)..... -55 dBc
- Power output +5 dBm
- Noise output -55 dBm/MHz

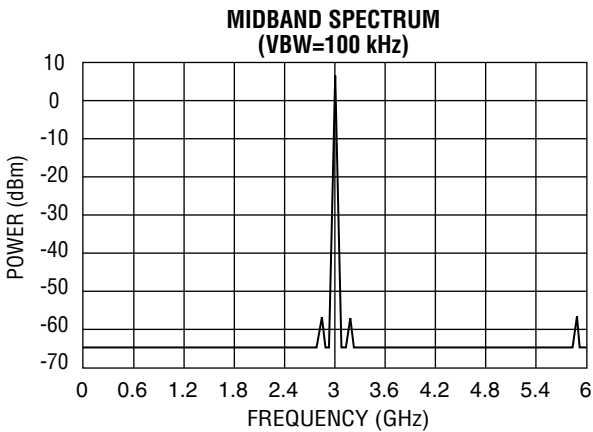

This integrated 3 stage, (X20) active multiplier subsystem is suitable for receiver LO generation using a reference VHF stabilized or voltage-tuned input source. Industry standard size amplifier and multiplier modules are used internally to make the unit easily modified for custom frequencies. These microstrip multiplier modules (“FEM” and “FOM” series) are also available as individual “drop-in” components. Intermediate outputs at X5 and X10 are available as an option as well.

2 TO 18 GHz BIPOLAR/SRD/MESFET COMB GENERATOR

MODEL: EOM0218HW4

FEATURES

- RF output..... 2 to 18 GHz
- RF input 0.5 to 1.5 GHz
- High multiplication ratios
- Integrated input power amplifier
- Packaging..... Hermetically sealed

This unit is suitable for high-frequency LO generation using a lower frequency phase stable reference. The output spectrum is easily filtered, due to the large comb spacing (high input frequency and multiplication orders). In addition, an input low noise power amplifier is provided to allow seamless integration with a +10 dBm input source.

NOTES:

1. Unit's mounting surface shall be attached to a heatsink capable of dissipating the devices power consumption without exceeding the operating temperature limits.
2. Refer to the actual device specification sheet for bias requirements. Negative bias input voltage (v-) may not be included on certain models.
3. Unless noted on the specification sheet, when negative bias is required, do not power the unit with positive bias for more than one second without the negative bias being applied.

Questions and Answers about...

FREQUENCY MULTIPLIERS

Q1: What do I need a frequency multiplier for?

A1: In general, a frequency multiplier translates an input frequency range to an output one, the output one being a multiple of the input. This is useful when an output signal is really needed higher than an available input source can supply. It could cost quite a lot to buy a source at higher frequencies. A better cost approach would be to use a less costly one, and just multiply the signal.

Q2: What specifications are important for a multiplier, and which ones should be given the most consideration?

A2: On page 380, some general rules and typical values are presented. Some important insights can be found by considering the way or system in which the multiplier will be used. It could be useful to examine the desired system specifications, in particular spurious rejection.

Q3: I need a custom multiplier, not shown in the catalog, what should be done next?

A3: Try to locate a somewhat similar product and identify the differences. Contact MITEQ for additional technical support.

Q4: I have a military and/or space multiplier requirement, and I cannot find any indication that MITEQ has produced such products. Is this a problem?

A4: MITEQ regularly gets such multiplier requirements. They are reviewed, and as such these custom multipliers are specific to a unique situation, and are not shown in our catalog.

Q5: I need a multiplier system, which includes non-multiplier type structures. Can MITEQ manufacture these type of systems and what sort of quantities, can MITEQ handle?

A5: A considerable amount of MITEQ's multiplier business includes small quantity custom products. Depending on future order potential and how much your budget can allow, all sorts of possibilities exist. Some of MITEQ's largest multiplier orders fit in this category.

Q6: What system precautions are important when specifying multiplier component specifications?

A6: One or more multipliers are often employed to upconvert a lower frequency stable reference oscillator into the system microwave operating frequency. Since active gain and filter stages are often necessary, one must insure that all multiplier output harmonics of the input reference frequency are adequately suppressed and the output power to noise floor ratio is compatible with the system phase noise specification. Since one or more gain stages of an active multiplier are saturated, AM noise is not usually a consideration.

Q7: What types of frequency multiplier circuits are available?**A7:** In order of increasing complexity:

- Single or single antiparallel pair Schottky diodes
- Single-, double- or triple-balanced Schottky diodes with baluns
- Active amplifiers and/or MMICS
- SRD (step-recovery diode) circuits
- Varactor diodes, resistive loaded
- Varactor diodes, regenerative

Q8: What precaution is necessary when specifying a multiplier to be followed by an active (and saturated) gain stage?

A8: If the amplifier is high gain with large bandwidth and saturates at +10 dBm, then the highest level multiplier output will produce +10 dBm output. However, if the fifth harmonic is desired from the multiplier but the third is more efficient by 6 dB, then the 5X output will be suppressed by the gain difference. This can be avoided by filtering the third harmonic or utilizing a multiplier with tuned baluns (MITEQ type FEM, FOM).

Q9: Can ordinary double- or triple-balanced mixers be used as multipliers?

A9: Yes, particularly as doublers, when the RF and LO are the same input frequency and the SUM (2RF) is extracted from the highest frequency port of the mixer. The total input power should be sufficient to turn on the diodes. The MITEQ 4 to 40 GHz triple-balanced mixer is available with an internal power splitter to direct the input energy to the LO and IF port (2 to 20 GHz) and recover the 4 to 40 GHz output at the RF port.

Q10: When is it wise to use a Schottky diode multiplier and when is an SRD or varactor type more suitable?

A10: Schottky diode multipliers are lowest cost and require the least input power (+10 dBm). Output noise is at room temperature (KTBW). The resulting current waveforms, however, have a high duty cycle (i.e., square wave = 50%) and therefore, higher multiplier harmonics above the fifth decay quickly. Step-recovery diodes have impulsive waveforms with comb-like output spectrums. The input circuit is more complex requiring a compromise between bandwidth and efficient coupling to the low diode series resistance. The required input power is a function of the SRD capacitance and quickly rises with frequency (+20 dBm typical at 1 GHz). The hyper abrupt varactor diode (indistinguishable at high frequencies from the SRD) yields the highest output powers and efficiency, provided that unwanted sidebands are reactively terminated. MITEQ has successfully made efficient frequency doublers and prescalers (halvers) at 10 and 20 GHz.
